

Tooth Implants Chilliwack

A maxillofacial implant is a man-made tooth and root replacement utilized to prop up other dental restorations that resemble a single tooth or a group of teeth. Implants once fused to the bone, give a durable foundation for artificial or false teeth. Fixed bridges and dentures that are positioned on top of implants will not drift or slip in the oral cavity, which makes it easier to complete tasks like eating and speaking. A secure fit will help the placed fixtures like dentures, crowns or caps, and bridges feel more natural and organic as opposed to traditional bridge and denture appliances.

Tooth implants may be a nice option for the patients who might not find ordinary bridges or dentures comfortable or even feasible, due to sore spots, inadequate ridges or gagging. In addition, conventional tooth bridges need to be secured to surrounding teeth on both sides of the open space left by the absent teeth. The benefits of using implants over a bridge is that no adjacent teeth need to be readied and manipulated to hold your new replacement fixture in place.

In order to prop up healthy implants, individuals require ample jawbone for support and must have fit gums. Plus, an extremely regimented hygiene program with regular oral cleanings are quite important to the overall success of implants, so clients must have the ability to provide ample commitment to keeping the structures and replacements healthy.
